Column-Oriented Database Systems
VLDB 2009 Tutorial

Part 1: Stavros Harizopoulos (HP Labs)

Part 2: Daniel Abadi (Yale)
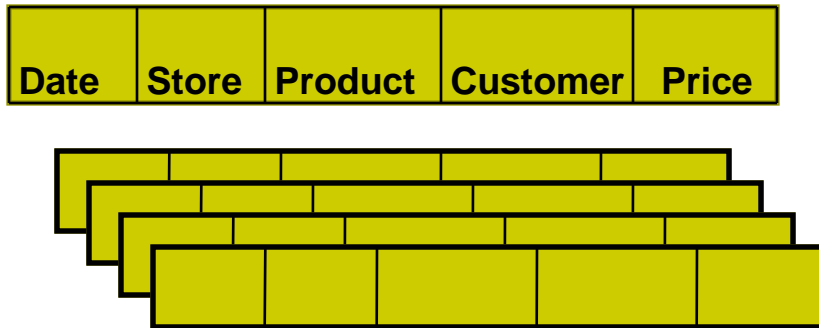

Part 3: Peter Boncz (CWI)
What is a column-store?

row-store

Date	Store	Product	Customer	Price

column-store

| Date | | Store | | Product | | Customer | | Price |

+ easy to add/modify a record

- might read in unnecessary data

+ only need to read in relevant data
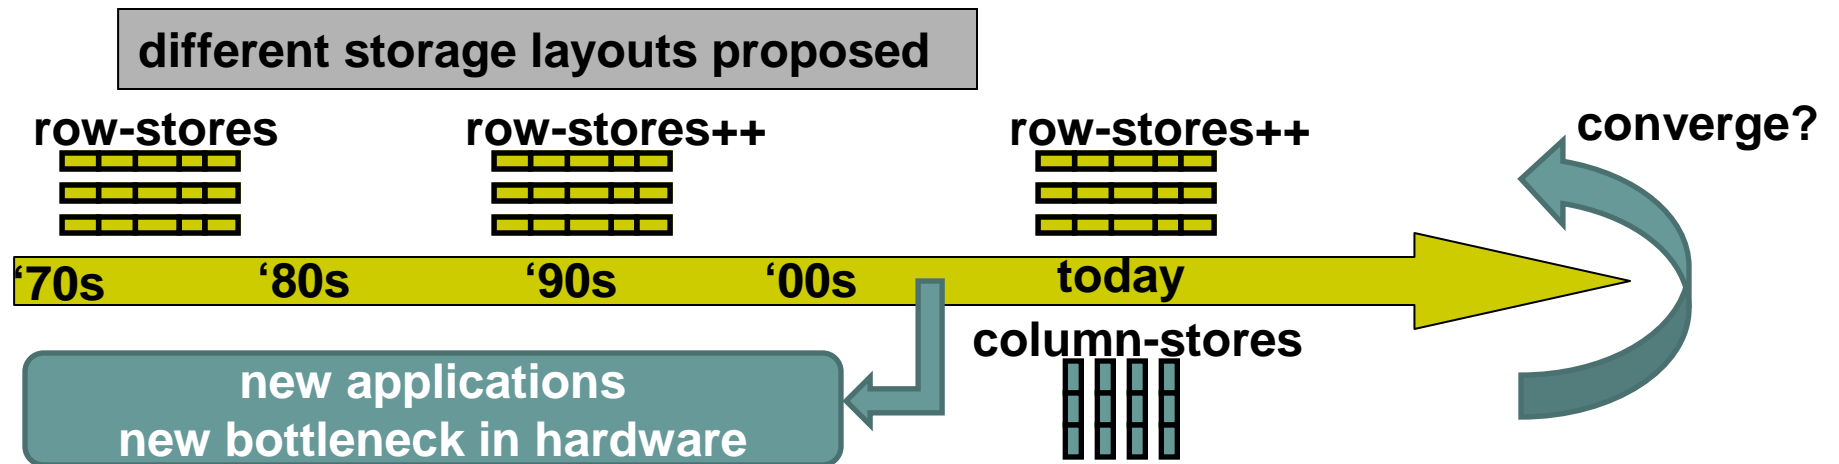

- tuple writes require multiple accesses

=> *suitable for read-mostly, read-intensive, large data repositories*

Are these two fundamentally different?

- The only fundamental difference is the storage layout
- However: we need to look at the big picture

- How did we get here, and where we are heading   **Part 1**
- What are the column-specific optimizations?   **Part 2**
- How do we improve CPU efficiency when operating on Cs   **Part 3**

Outline

- ### Part 1: Basic concepts — *Stavros*
    - Introduction to key features
    - From DSM to column-stores and performance tradeoffs
    - Column-store architecture overview
    - Will rows and columns ever converge?

- ### Part 2: Column-oriented execution — *Daniel*

- ### Part 3: MonetDB/X100 and CPU efficiency — *Peter*

Telco Data Warehousing example

- Typical DW installation

- Real-world example

"One Size Fits All? - Part 2: Benchmarking Results" Stonebraker et al. CIDR 2007

dimension tables

account

or RAM

fact table

usage

source

toll

star schema

QUERY 2
```
SELECT account.account_number,
sum (usage.toll_airtime),
sum (usage.toll_price)
FROM usage, toll, source, account
WHERE usage.toll_id = toll.toll_id
AND usage.source_id = source.source_id
AND usage.account_id = account.account_id
AND toll.type_ind in ('AE'. 'AA')
AND usage.toll_price > 0
AND source.type != 'CIBER'
AND toll.rating_method = 'IS'
AND usage.invoice_date = 20051013
GROUP BY account.account_number
```

	Column-store	Row-store
Query 1	2.06	300
Query 2	2.20	300
Query 3	0.09	300
Query 4	5.24	300
Query 5	2.88	300

Why? Three main factors (next slides)

Telco example explained (1/3):
read efficiency

row store	**column store**
read pages containing entire rows

one row = 212 columns!

is this typical? (it depends)

| **What about vertical partitioning?** |
| **(it does not work with ad-hoc** |
| **queries)** |

read only columns needed

in this example: 7 columns

caveats:
- "select * " not any faster
- clever disk prefetching
- clever tuple reconstruction

# Telco example explained (2/3): *compression efficiency*

- Columns compress better than rows

    - Typical row-store compression ratio 1 : 3

    - Column-store 1 : 10

- Why?

    - Rows contain values from different domains

        => more entropy, difficult to dense-pack

    - Columns exhibit significantly less entropy

    - Examples:

        > **Male, Female, Female, Female, Male**
        > **1998, 1998, 1999, 1999, 1999, 2000**

    - Caveat: CPU cost (use lightweight compression)

Telco example explained (3/3): *sorting & indexing efficiency*

- Compression and dense-packing free up space

  - Use multiple overlapping column collections

  - Sorted columns compress better

  - Range queries are faster

  - Use sparse clustered indexes

What about heavily-indexed row-stores?
(works well for single column access,
cross-column joins become increasingly expensive)

Additional opportunities for column-stores

- Block-tuple / vectorized processing
  - Easier to build block-tuple operators
    - Amortizes function-call cost, improves CPU cache performance
  - Easier to apply vectorized primitives
    - Software-based: bitwise operations
    - Hardware-based: SIMD   **Part 3**

- Opportunities with compressed columns
  - *Avoid* decompression: operate directly on compressed
  - *Delay* decompression (and tuple reconstruction)   **more in Part 2**
    - Also known as: *late materialization*

- Exploit columnar storage in other DBMS components
  - Physical design (both static and dynamic)   See: *Database Cracking*, from CWI

Effect on C-Store performance

"Column-Stores vs Row-Stores: How Different are They Really?" Abadi, Hachem, and Madden. SIGMOD 2008.

Average for SSBM queries on C-store

original C-store

column-oriented join algorithm

enable compression & operate on compressed

enable late materialization
Summary of column-store key features
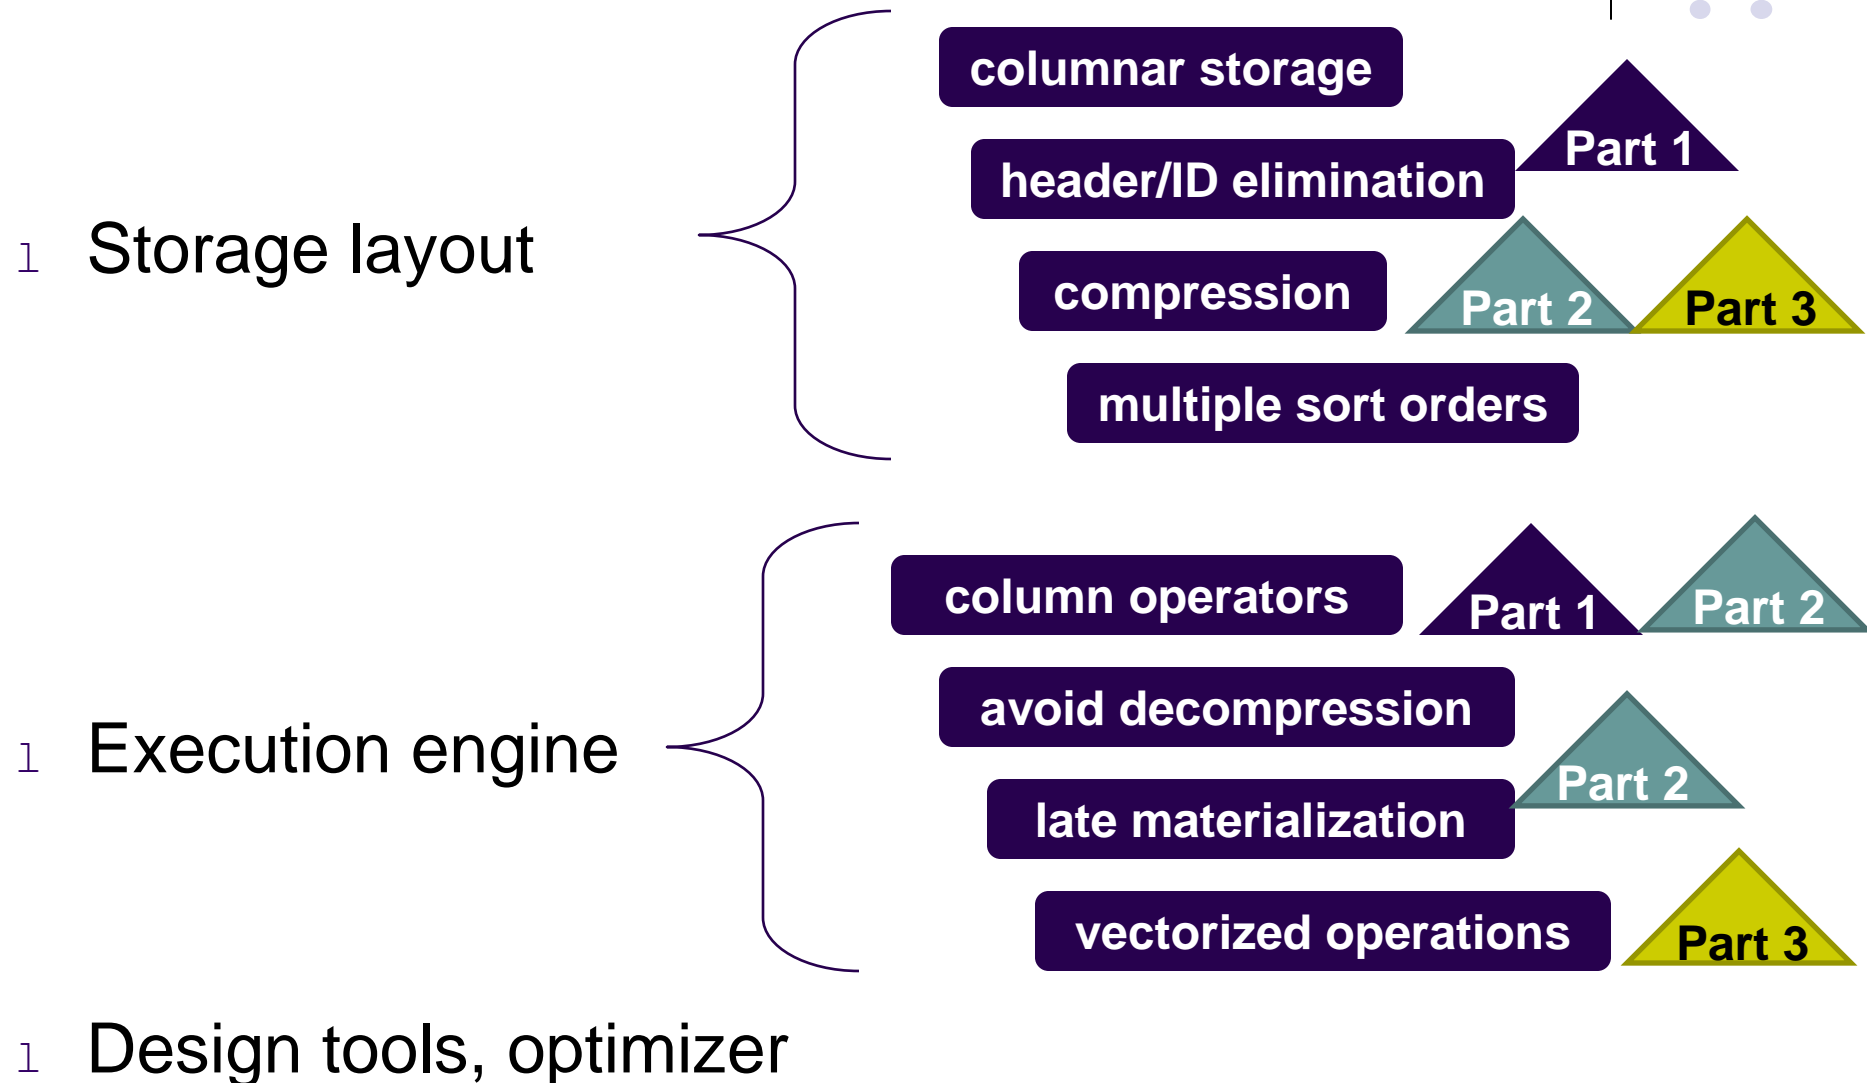

- Storage layout

  - **columnar storage**
  - **header/ID elimination**
  - **compression**
  - **multiple sort orders**

  Part 1   Part 2   Part 3

- Execution engine

  - **column operators**
  - **avoid decompression**
  - **late materialization**
  - **vectorized operations**

  Part 1   Part 2   Part 2   Part 3

- Design tools, optimizer

Outline

l Part 1: Basic concepts — *Stavros*

- l Introduction to key features
- l From DSM to column-stores and performance tradeoffs
- l Column-store architecture overview
- l Will rows and columns ever converge?

l Part 2: Column-oriented execution — *Daniel*

l Part 3: MonetDB/X100 and CPU efficiency — *Peter*

From DSM to Column-stores

70s -1985:

TOD: Time Oriented Database – Wiederhold et al. "A Modular, Self-Describing Clinical Databank System," *Computers and Biomedical Research, 1975* More 1970s: Transposed files, Lorie, Batory, Svensson

"An overview of cantor: a new system for data analysis" Karasalo, Svensson, SSDBM 1983

1985: DSM paper

"A decomposition storage model" Copeland and Khoshafian. SIGMOD 1985.

1990s: Commercialization through SybaseIQ

Late 90s – 2000s: Focus on main-memory performance

- DSM "on steroids" [1997 – now]   CWI: MonetDB
- Hybrid DSM/NSM [2001 – 2004]   Wisconsin: PAX, Fractured Mirrors

Michigan: Data Morphing   CMU: Clotho

2005 – : Re-birth of read-optimized DSM as "column-store"

MIT: C-Store   CWI: MonetDB/X100   10+ startups

# The original DSM paper

"A decomposition storage model" Copeland and Khoshafian. SIGMOD 1985.

- Proposed as an alternative to NSM
- 2 indexes: clustered on ID, non-clustered on value
- Speeds up queries projecting few columns
- Requires more storage

Memory wall and PAX

- 90s: Cache-conscious research

from: "Cache Conscious Algorithms for Relational Query Processing." Shatdal, Kant, Naughton. VLDB 1994.

to: "Database Architecture Optimized for the New Bottleneck: Memory Access." Boncz, Manegold, Kersten. VLDB 1999.

and: "DBMSs on a modern processor: Where does time go?" Ailamaki, DeWitt, Hill, Wood. VLDB 1999.

- PAX: Partition Attributes Across

  - Retains NSM I/O pattern
  - Optimizes cache-to-RAM communication

"Weaving Relations for Cache Performance." Ailamaki, DeWitt, Hill, Skounakis, VLDB 2001.

PAX PAGE

PAGE HEADER		0962	7658
3859	5523		

Jane	John	Jim	Susan

30	52	45	20

More hybrid NSM/DSM schemes

- Dynamic PAX: Data Morphing

  "Data morphing: an adaptive, cache-conscious storage technique." Hankins, Patel, VLDB 2003.

- Clotho: custom layout using scatter-gather I/O

  "Clotho: Decoupling Memory Page Layout from Storage Organization." Shao, Schindler, Schlosser, Ailamaki, and Ganger. VLDB 2004.

- Fractured mirrors

  - Smart mirroring with both NSM/DSM copies
"A Case For Fractured Mirrors." Ramamurthy, DeWitt, Su, VLDB 2002.

MonetDB (more in Part 3)

- Late 1990s, CWI: Boncz, Manegold, and Kersten

- Motivation:

  - Main-memory

  - Improve computational efficiency by avoiding expression interpreter

  - DSM with virtual IDs natural choice

  - Developed new query execution algebra

- Initial contributions:

  - Pointed out memory-wall in DBMSs

  - Cache-conscious projections and joins

  - …

2005: the (re)birth of column-stores

- New hardware and application realities
  - Faster CPUs, larger memories, disk bandwidth limit
  - Multi-terabyte Data Warehouses
- New approach: combine several techniques
  - Read-optimized, fast multi-column access,
    disk/CPU efficiency, light-weight compression

- C-store paper:
  - First comprehensive design description of a column-store
- MonetDB/X100
  - "proper" disk-based column store
- Explosion of new products

Performance tradeoffs: columns vs. rows

DSM traditionally was not favored by technology trends
How has this changed?

- Optimized DSM in "Fractured Mirrors," 2002

- "Apples-to-apples" comparison

  "Performance Tradeoffs in Read-Optimized Databases" Harizopoulos, Liang, Abadi, Madden, VLDB'06

- Follow-up study

  "Read-Optimized Databases, In-Depth" Holloway, DeWitt, VLDB'08

- Main-memory DSM vs. NSM

  "DSM vs. NSM: CPU performance tradeoffs in block-oriented query processing" Boncz, Zukowski, Nes, DaMoN'08

- Flash-disks: a come-back for PAX?

  "Fast Scans and Joins Using Flash Drives" Shah, Harizopoulos, Wiener, Graefe. DaMoN'08

  "Query Processing Techniques for Solid State Drives" Tsirogiannis, Harizopoulos, Shah, Wiener, Graefe, SIGMOD'09

n-Oriented Databa

Fractured mirrors: a closer look

- Store DSM relations inside a B-tree
  - Leaf nodes contain values
  - Eliminate IDs, amortize header overhead
  - Custom implementation on Shore

"A Case For Fractured Mirrors" Ramamurthy, DeWitt, Su, VLDB 2002.

Tuple Header	TID	Column Data
	1	a1
	2	a2
	3	a3
	4	a4
	5	a5

sparse B-tree on ID

3

| 1 | a1 | 2 | a2 | 3 | a3 |

| 4 | a4 | 5 | a5 |

| 1 | a1 | a2 | a3 |

| 4 | a4 | a5 |
Similar: storage density comparable to column stores

"Efficient columnar storage in B-trees" Graefe. Sigmod Record 03/2007.

Fractured mirrors: performance

From PAX paper:

NSM/PAX/DSM Elapsed Time

regular DSM

NSM — ▲
PAX — ■
DSM — ●

elapsed time (seconds)

number of attributes in query

time

column?

row

column?

columns projected:
1   2   3   4   5

Lineitem (TPCH) 1GB

optimized DSM

NSM — ▲
Page-at-a-time — ■
Chunk-Merge — ●

Seconds

No. of Attributes
- Chunk-based tuple merging
  - Read in segments of M pages
  - Merge segments in memory
  - Becomes CPU-bound after 5 pages
Column-scanner implementation

"Performance Tradeoffs in Read-Optimized Databases" Harizopoulos, Liang, Abadi, Madden, VLDB'06

row scanner

Scan performance

- Large prefetch hides disk seeks in columns
- Column-CPU efficiency with lower selectivity
- Row-CPU suffers from memory stalls
- Memory stalls disappear in narrow tuples
- Compression: similar to narrow

not shown,
details in the paper

Even more results

"Read-Optimized Databases, In-Depth" Holloway, DeWitt, VLDB'08
- Same engine as before
- Additional findings

narrow & compressed tuple: CPU-bound!

Legend (right chart):
- C-25%
- C-10%
- R-50%

X-axis: Columns Returned
Y-axis: Time (s)
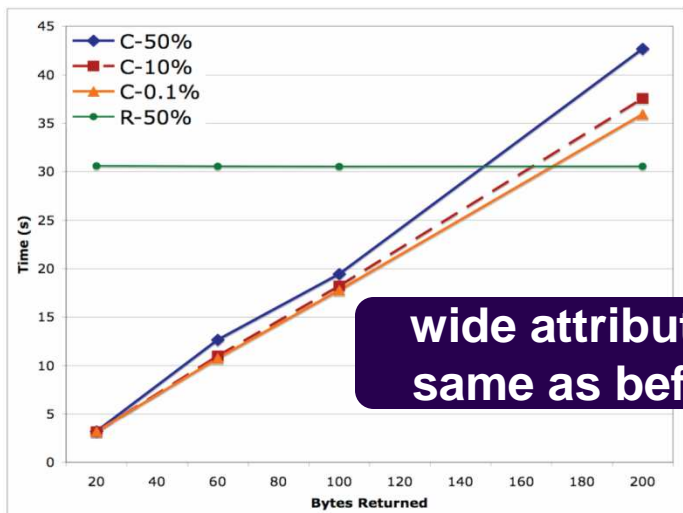

wide attributes: same as before

Legend (left chart):
- C-50%
- C-10%
- C-0.1%
- R-50%

X-axis: Bytes Returned
Y-axis: Time (s)
Non-selective queries, narrow tuples, favor well-compressed rows

Materialized views are a win

Scan times determine early materialized joins

Column-joins are covered in part 2!

Speedup of columns over rows

"Performance Tradeoffs in Read-Optimized Databases" Harizopoulos, Liang, Abadi, Madden, VLDB'06

(cpdb)

cycles per disk byte

144 — 72 — 36 — 18 — 9

tuple width: 8 12 16 20 24 28 32 36

l Rows favored by narrow tuples and low *cpdb*

　 l Disk-bound workloads have higher *cpdb*

Varying prefetch size

no competing disk traffic

time (sec) — vertical axis: 0, 10, 20, 30, 40

- Column 2
- Column 8
- Column 16
- Column 48 (x 128KB)

Row (any prefetch size)

selected bytes per tuple — horizontal axis: 4, 8, 12, 16, 20, 24, 28, 32
l No prefetching hurts columns in single scans

Varying prefetch size

with competing disk traffic
- No prefetching hurts columns in single scans
- Under competing traffic, columns outperform rows for any prefetch size

CPU Performance

"DSM vs. NSM: CPU performance trade offs in block-oriented query processing" Boncz, Zukowski, Nes, DaMoN'08

- Benefit in on-the-fly conversion between NSM and DSM
- DSM: sequential access (block fits in L2), random in L1
- NSM: random access, SIMD for grouped Aggregation
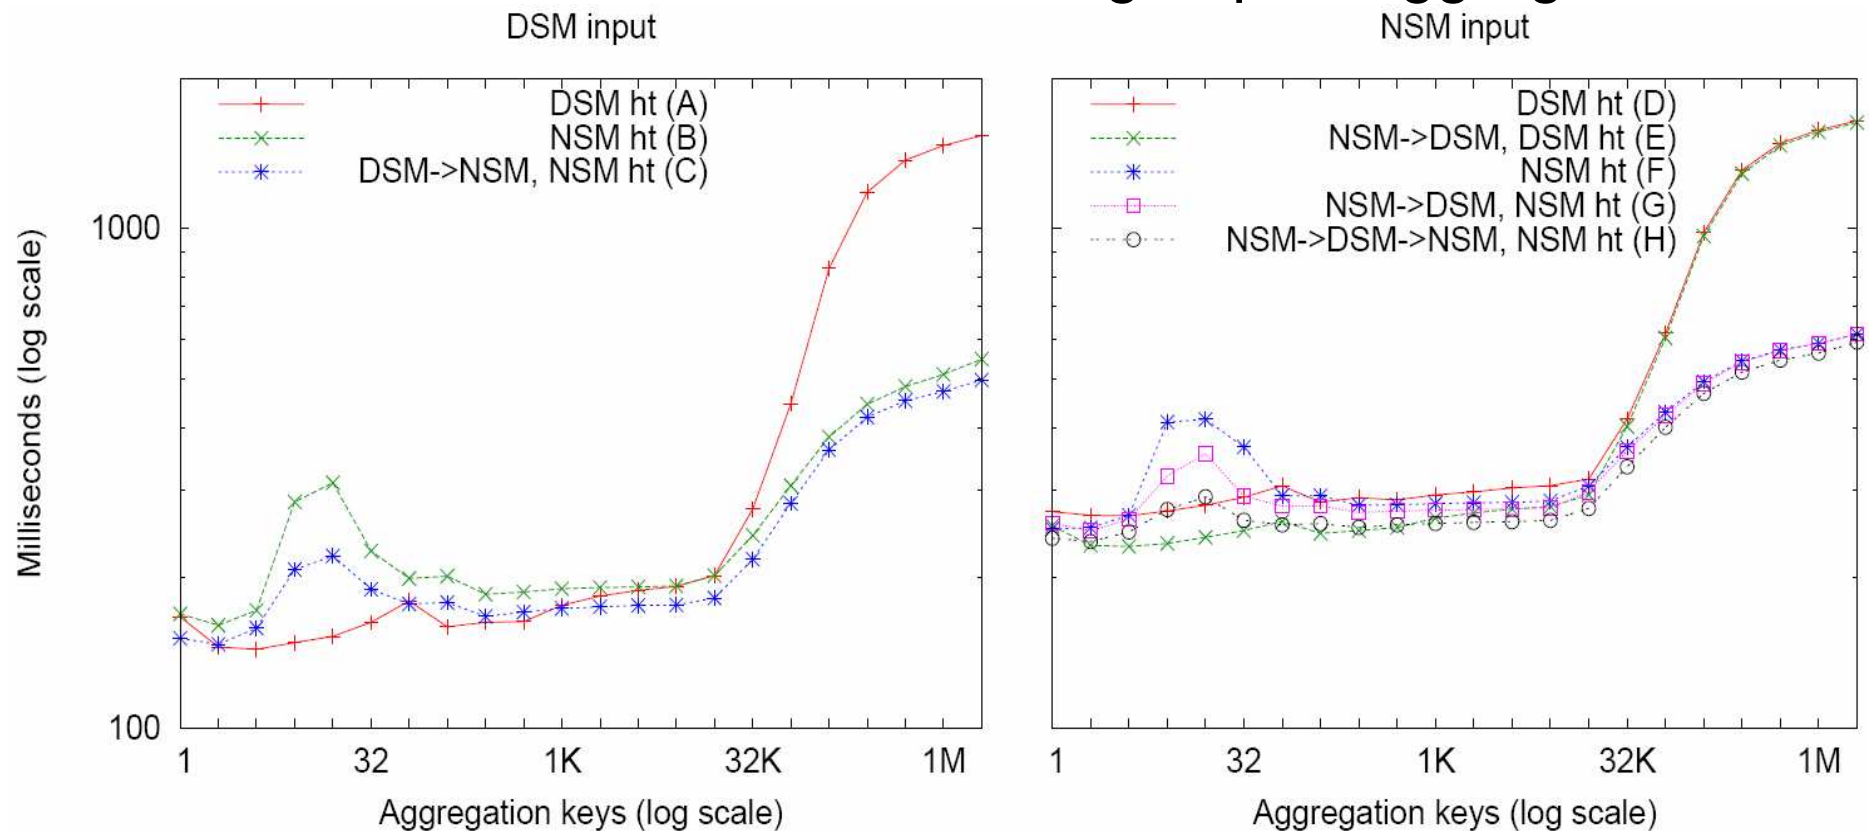

Figure 5: TPC-H Q1, with a varying number of keys and different data organizations (ht − hash table)

New storage technology: Flash SSDs

- Performance characteristics
    - very fast random reads, slow random writes
    - fast sequential reads and writes
- Price per bit (capacity follows)
    - cheaper than RAM, order of magnitude more expensive than Disk
- Flash Translation Layer introduces unpredictability
    - avoid random writes!
- Form factors not ideal yet
    - SSD (Ł small reads still suffer from SATA overhead/OS limitations)
    - PCI card (Ł high price, limited expandability)

- Boost Sequential I/O in a simple package
    - Flash RAID: very tight bandwidth/cm³ packing (4GB/sec inside the box)
- Column Store Updates
    - useful for delta structures and logs
- Random I/O on flash fixes unclustered index access
    - still suboptimal if I/O block size > record size
    - therefore column stores profit mush less than horizontal stores
- Random I/O useful to exploit secondary, tertiary table orderings
    - the larger the data, the deeper clustering one can exploit

Even faster column scans on flash SSDs

> 30K Read IOps, 3K Write Iops
> 250MB/s Read BW, 200MB/s Write

- New-generation SSDs
  - Very fast random reads, slower random writes
  - Fast sequential RW, comparable to HDD arrays
- No expensive seeks across columns
- FlashScan and Flashjoin: PAX on SSDs, inside Postgres
> "Query Processing Techniques for Solid State Drives" Tsirogiannis, Harizopoulos, Shah, Wiener, Graefe, SIGMOD'09

mini-pages with no qualified attributes are not accessed

Column-scan performance over time

regular DSM (2001)
from 7x slower

column-store (2006)

..to 1.2x slower

..to 2x slower

optimized DSM (2002)
..to same

and 3x faster!
SSD Postgres/PAX (2009)

Column-Oriented Databa

Outline

- Part 1: Basic concepts — *Stavros*
    - Introduction to key features
    - From DSM to column-stores and performance tradeoffs
    - Column-store architecture overview
    - Will rows and columns ever converge?

- Part 2: Column-oriented execution — *Daniel*

- Part 3: MonetDB/X100 and CPU efficiency — *Peter*

Architecture of a column-store

storage layout

- read-optimized: dense-packed, compressed
- organize in extends, batch updates
- multiple sort orders
- sparse indexes

engine

- block-tuple operators
- new access methods
- optimized relational operators

system-level

- system-wide column support
- loading / updates
- scaling through multiple nodes
- transactions / redundancy

C-Store

> "C-Store: A Column-Oriented DBMS." Stonebraker et al. VLDB 2005.

l Compress columns

l No alignment

l Big disk blocks

l Only materialized views (perhaps many)

l Focus on Sorting not indexing

l Data ordered on anything, not just time

l Automatic physical DBMS design

l Optimize for grid computing

l Innovative redundancy

l Xacts – but no need for Mohan

l Column optimizer and executor

C-Store: only materialized views (MVs)

- Projection (MV) is some number of columns from a fact table
- Plus columns in a dimension table – with a 1-n join between Fact and Dimension table
- Stored in order of a storage key(s)
- Several may be stored!
- With a permutation, if necessary, to map between them
- Table (as the user specified it and sees it) is not stored!
- No secondary indexes (they are a one column sorted MV plus a permutation, if you really want one)

User view:
EMP (name, age, salary, dept)
Dept (dname, floor)

Possible set of MVs:
MV-1 (name, dept, floor) in floor order
MV-2 (salary, age) in age order
MV-3 (dname, salary, name) in salary order

Continuous Load and Query (Vertica)

Hybrid Storage Architecture

Trickle Load

> **Write Optimized Store (WOS)**

A   B   C

§ **Memory based**
§ **Unsorted / Uncompressed**
§ **Segmented**
§ **Low latency / Small quick inserts**

TUPLE MOVER Asynchronous Data Transfer

> **Read Optimized Store (ROS)**

• **On disk**
• **Sorted / Compressed**
• **Segmented**
• **Large data loaded direct**

A   B   C

(A B C | A)
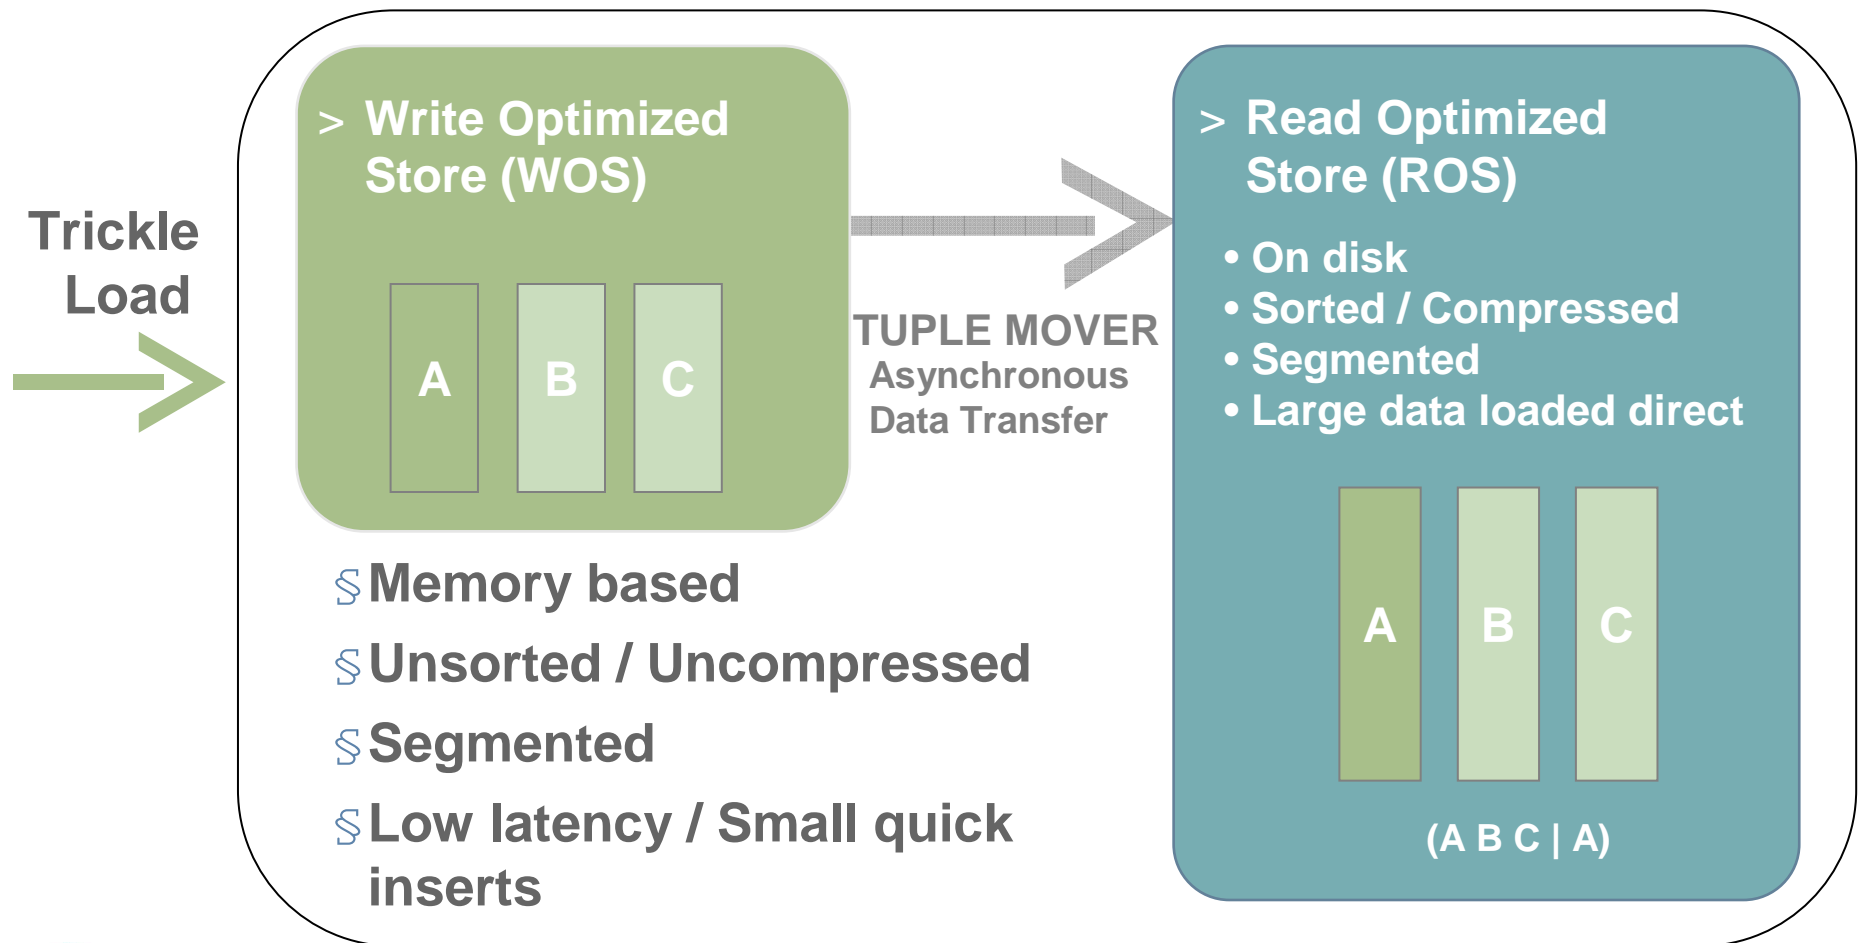

Loading Data (Vertica)

> **INSERT, UPDATE, DELETE**

> **Bulk and Trickle Loads**

　§ **COPY**

　§ **COPY DIRECT**

> **User loads data into logical Tables**

> **Vertica loads atomically into storage**

Write-Optimized Store (WOS)
In-memory
Automatic Tuple Mover

Read-Optimized Store (ROS)
On-disk
Applications for column-stores

- Data Warehousing
  - High end (clustering)
  - Mid end/Mass Market
  - Personal Analytics
- Data Mining
  - E.g. Proximity
- Google BigTable
- RDF
  - Semantic web data management
- Information retrieval
  - Terabyte TREC
- Scientific datasets
  - SciDB initiative
  - SLOAN Digital Sky Survey on MonetDB

List of column-store systems

- Cantor (history)
- Sybase IQ
- SenSage (former Addamark Technologies)
- Kdb
- 1010data
- MonetDB
- C-Store/Vertica
- X100/VectorWise
- KickFire
- SAP Business Accelerator
- Infobright
- ParAccel
- Exasol

Experiments

- Star Schema Benchmark (SSBM)

> Adjoined Dimension Column Index (ADC Index) to Improve Star Schema Query Performance". O'Neil et. al. ICDE 2008.

- Implemented by professional DBA
- Original row-store plus 2 column-store simulations on same row-store product
> "Column-Stores vs Row-Stores: How Different are They Really?" Abadi, Hachem, and Madden. SIGMOD 2008.

	Normal Row-Store	Vertically Partitioned Row-Store	Row-Store With All Indexes
Average	25.7	79.9	221.2

What's Going On? Vertical Partitions

- Vertical partitions in row-stores:
  - Work well when workload is known
  - ..and queries access disjoint sets of columns
  - See automated physical design

Tuple Header	TID	Column Data
	1	
	2	
	3	

- Do not work well as full-columns
  - TupleID overhead significant
  - Excessive joins

Queries touch 3-4 foreign keys in fact table, 1-2 numeric columns

Complete fact table takes up ~4 GB (compressed)

"Column-Stores vs. Row-Stores: How Different Are They Really?" Abadi, Madden, and Hachem. SIGMOD 2008.

Vertically partitioned tables take up 0.7-1.1 GB (compressed)

What's Going On? All Indexes Case

- Tuple construction
  - Common type of query:

    SELECT store_name, SUM(revenue)
    FROM Facts, Stores
    WHERE fact.store_id = stores.store_id
        AND stores.country = "Canada"
    GROUP BY store_name

  - Result of lower part of query plan is a set of TIDs that passed all predicates
  - Need to extract SELECT attributes at these TIDs
    - BUT: index maps value to TID
    - You really want to map TID to value (i.e., a vertical partition)

  Tuple construction is SLOW

So….

- All indexes approach is a poor way to simulate a column-store
- Problems with vertical partitioning are NOT fundamental
    - Store tuple header in a separate partition
    - Allow virtual TIDs
    - Combine clustered indexes, vertical partitioning
- So can row-stores simulate column-stores?
    - Might be possible, BUT:
        - Need better support for vertical partitioning at the storage layer
        - Need support for column-specific optimizations at the executer level
        - Full integration: buffer pool, transaction manager, ..
    - When will this happen?
        - Most promising features = soon

        > See Part 2, Part 3 for most promising features

        - ..unless new technology / new objectives change the game
          (SSDs, Massively Parallel Platforms, Energy-efficiency)

End of Part 1

Frame Of Reference Encoding

- **Encodes values as b bit offset from chosen frame of reference**

- **Special escape code (e.g. all bits set to 1) indicates a difference larger than can be stored in b bits**
  - **After escape code, original (uncompressed) value is written**

"Compressing Relations and Indexes" Goldstein, Ramakrishnan, Shaft, ICDE'98

Exceptions (see part 3 for a better way to deal with exceptions)
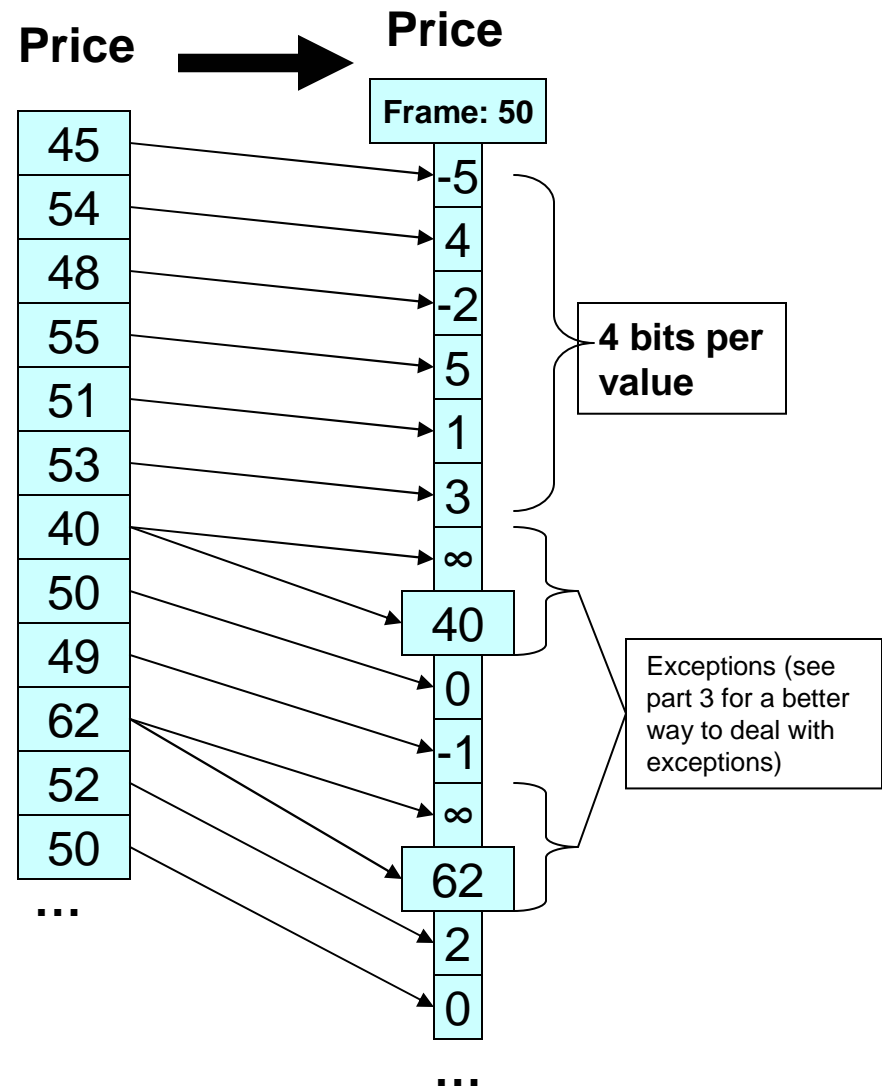

Differential Encoding

- Encodes values as b bit offset from previous value
- Special escape code (just like frame of reference encoding) indicates a difference larger than can be stored in b bits
  - After escape code, original (uncompressed) value is written
- Performs well on columns containing increasing/decreasing sequences
  - inverted lists
  - timestamps
  - object IDs
  - sorted / clustered columns

What Compression Scheme To Use?

Does column appear in the sort key?

yes   no

Is the average run-length > 2

yes   no

RLE

Differential Encoding

Are number of unique values < ~50000

no

yes

Does this column appear frequently in selection predicates?

yes   no

Is the data numerical and exhibit good locality?

yes   no

Frame of Reference Encoding

Leave Data Uncompressed

Bit-vector Compression

Dictionary Compression

OR

Heavyweight Compression
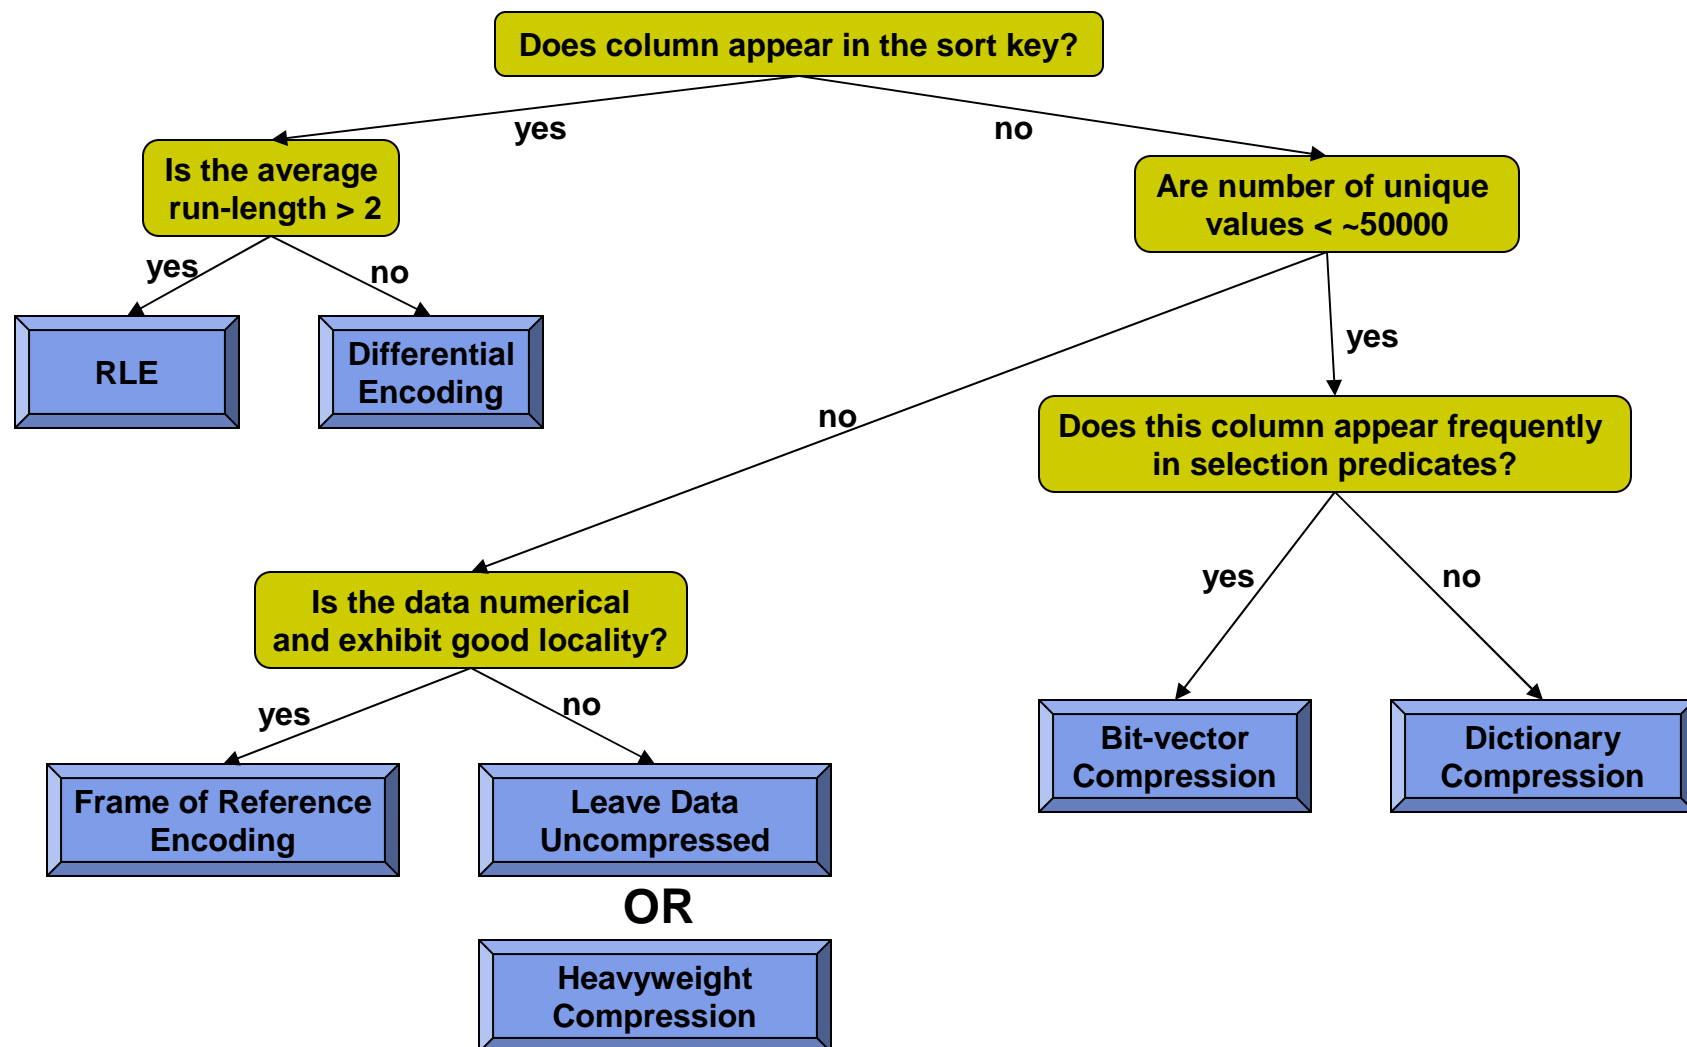

"Super-Scalar RAM-CPU Cache Compression"
Zukowski, Heman, Nes, Boncz, ICDE'06

Heavy-Weight Compression Schemes

Algorithm	Decompression Bandwidth
BZIP	10 MB/s
ZLIB	80 MB/s
LZO	300 MB/s

- Modern disk arrays can achieve > 1GB/s
- 1/3 CPU for decompression ⌐ 3GB/s needed

- **Lightweight compression schemes are better**
- **Even better: operate directly on compressed data**

"Integrating Compression and Execution in Column-Oriented Database Systems" Abadi et. al, SIGMOD '06

Operating Directly on Compressed Data

- **I/O - CPU tradeoff is no longer a tradeoff**

- **Reduces memory–CPU bandwidth requirements**

- **Opens up possibility of operating on multiple records at once**

Column-Oriented Database Systems

VLDB
2009
Tutorial

Tuple Materialization and
Column-Oriented Join Algorithms

"Materialization Strategies in a Column-Oriented DBMS" Abadi, Myers, DeWitt, and Madden. ICDE 2007.

"Self-organizing tuple reconstruction in column-stores", Idreos, Manegold, Kersten, SIGMOD'09

"Column-Stores vs Row-Stores: How Different are They Really?" Abadi, Madden, and Hachem. SIGMOD 2008.

"Query Processing Techniques for Solid State Drives" Tsirogiannis, Harizopoulos Shah, Wiener, and Graefe. SIGMOD 2009.

"Cache-Conscious Radix-Decluster Projections", Manegold, Boncz, Nes, VLDB'04
When should columns be projected?

- **Where should column projection operators be placed in a query plan?**
    - **Row-store:**
        - **Column projection involves removing unneeded columns from tuples**
        - **Generally done as early as possible**
    - **Column-store:**
        - **Operation is almost completely opposite from a row-store**
        - **Column projection involves reading needed columns from storage and extracting values for a listed set of tuples**
            - **This process is called "materialization"**
        - **Early materialization: project columns at beginning of query plan**
            - **Straightforward since there is a one-to-one mapping across columns**
        - **Late materialization: wait as long as possible for projecting columns**
            - **More complicated since selection and join operators on one column obfuscates mapping to other columns from same table**
        - **Most column-stores construct tuples and column projection time**
            - **Many database interfaces expect output in regular tuples (rows)**
            - **Rest of discussion will focus on this case**

When should tuples be constructed?

Select + Aggregate

4	2	2	7
4	1	3	13

"Materialization Strategies in a Column-Oriented DBMS"
Abadi, Myers, DeWitt, and Madden. ICDE 2007.

For plans without joins, late materialization is a win

QUERY:

```
SELECT C₁, SUM(C₂)
FROM table
WHERE (C₁ < CONST) AND
      (C₂ < CONST)
GROUP BY C₁
```
l **Ran on 2 compressed columns from TPC-H scale 10 data**

"Materialization Strategies in a Column-Oriented DBMS"
Abadi, Myers, DeWitt, and Madden. ICDE 2007.

Even on uncompressed data, late materialization is still a win
QUERY:

SELECT C_1, SUM(C_2)
FROM table
WHERE (C_1 < CONST) AND
        (C_2 < CONST)
GROUP BY C_1

l **Materializing late still works best**

What about for plans with joins?

Select R1.B, R1.C, R2.E, R2.H, R3.F
From R1, R2, R3
Where R1.A = R2.D AND R2.G = R3.K

What about for plans with joins?

Select R1.B, R1.C, R2.E, R2.H, R3.F
From R1, R2, R3
Where R1.A = R2.D AND R2.G = R3.K

Customers
Late Materialized Join Performance

- Naïve LM join about 2X slower than EM join on typical queries (due to random I/O)
  - This number is very dependent on
    - Amount of memory available
    - Number of projected attributes
    - Join cardinality
- But we can do better
  - Invisible Join
  - Jive/Flash Join
  - Radix cluster/decluster join

Invisible Join

"Column-Stores vs Row-Stores: How Different are They Really?" Abadi, Madden, and Hachem. SIGMOD 2008.

- Designed for typical joins when data is modeled using a star schema
  - One ("fact") table is joined with multiple dimension tables
- Typical query:

```
select c_nation, s_nation, d_year,
        sum(lo_revenue) as revenue
from customer, lineorder, supplier, date
where lo_custkey = c_custkey
    and lo_suppkey = s_suppkey
    and lo_orderdate = d_datekey
    and c_region = 'ASIA'
    and s_region = 'ASIA'
    and d_year >= 1992 and d_year <= 1997
group by c_nation, s_nation, d_year
order by d_year asc, revenue desc;
```

Invisible Join

Invisible Join

- **Bottom Line**

    - **Many data warehouses model data using star/snowflake schemes**

    - **Joins of one (fact) table with many dimension tables is common**

    - **Invisible join takes advantage of this by making sure that the table that can be accessed in position order is the fact table for each join**

    - **Position lists from the fact table are then intersected (in position order)**

    - **This reduces the amount of data that must be accessed out of order from the dimension tables**

    - **"Between-predicate rewriting" trick not relevant for this discussion**

Still accessing table out of order

"Fast Joins using Join Indices". Li and Ross, VLDBJ 8:1-24, 1999.

"Query Processing Techniques for Solid State Drives". Tsirogiannis, Harizopoulos et. al. SIGMOD 2009.

Re-use permitted when acknowledging the original © Stavros Harizopoulos, Daniel Abadi, Peter Boncz (2009)

Jive/Flash Join

1. Add column with dense ascending integers from 1

2. Sort new position list by second column

3. Probe projected column in order using new sorted position list, keeping first column from position list around

4. Sort new result by first column

2	CHINA
Jive/Flash Join

- **Bottom Line**
  - **Instead of probing projected columns from inner table out of order:**
    - **Sort join index**
    - **Probe projected columns in order**
    - **Sort result using an added column**
  - **LM vs EM tradeoffs:**
    - **LM has the extra sorts (EM accesses all columns in order)**
    - **LM only has to fit join columns into memory (EM needs join columns and all projected columns)**
      - **Results in big memory and CPU savings (see part 3 for why there is CPU savings)**
    - **LM only has to materialize relevant columns**
    - **In many cases LM advantages outweigh disadvantages**
  - **LM would be a clear winner if not for those pesky sorts … can we do better?**

Radix Cluster/Decluster

- The full sort from the Jive join is actually overkill

  - We just want to access the storage blocks in order (we don't mind random access within a block)

  - So do a radix sort and stop early

  - By stopping early, data within each block is accessed out of order, but in the order specified in the original join index

    - Use this pseudo-order to accelerate the post-probe sort as well

•"Database Architecture Optimized for the New Bottleneck: Memory Access" VLDB'99
•"Generic Database Cost Models for Hierarchical Memory Systems", VLDB'02 (all Manegold, Boncz, Kersten)

"Cache-Conscious Radix-Decluster Projections", Manegold, Boncz, Nes, VLDB'04

Radix Cluster/Decluster

l Bottom line

 l Both sorts from the Jive join can be significantly reduced in overhead

 l Only been tested when there is sufficient memory for the entire join index to be stored three times

 l Technique is likely applicable to larger join indexes, but utility will go down a little

 l Only works if random access within a storage block

 l Don't want to use radix cluster/decluster if you have variable-width column values or compression schemes that can only be decompressed starting from the beginning of the block

LM vs EM joins

- l Invisible, Jive, Flash, Cluster, Decluster techniques contain a bag of tricks to improve LM joins

- l Research papers show that LM joins become 2X faster than EM joins (instead of 2X slower) for a wide array of query types

Tuple Construction Heuristics

- **For queries with selective predicates, aggregations, or compressed data, use late materialization**

- **For joins:**
  - **Research papers:**
    - **Always use late materialization**
  - **Commercial systems:**
    - **Inner table to a join often materialized before join (reduces system complexity):**
    - **Some systems will use LM only if columns from inner table can fit entirely in memory**

Outline

- Computational Efficiency of DB on modern hardware

  - how column-stores can help here

  - Keynote revisited: MonetDB & VectorWise in more depth

- CPU efficient column compression

 - vectorized decompression

- Conclusions

  - future work

MATERIALIZED intermediate results

a column-store

- ~~"save disk I/O when scan-intensive queries... need a few columns"~~
- ~~"avoid an expression interpreter to improve computational efficiency"~~

How?

- RISC query algebra: hard-coded semantics
  - Decompose complex expressions in multiple operations
- Operators only handle **simple arrays**
  - No code that handles slotted buffered record layout
- Relational algebra becomes **array manipulation language**
  - Often SIMD for free

  - Plus: use of *cache-conscious* algorithms for Sort/Aggr/Join

a Faustian pact

- You want efficiency
  - Simple hard-coded operators
- I take scalability
  - Result materialization

Tutorial

Efficient Column Store Compression

vectorwise

Key Ingredients

"Super-Scalar RAM-CPU Cache Compression"
Zukowski, Heman, Nes, Boncz, ICDE'06

- Compress relations on a per-column basis
  - Columns compress well
- Decompress small *vectors* of tuples from a column into the CPU cache
  - Minimize main-memory overhead
- Use light-weight, CPU-efficient algorithms
  - Exploit processing power of modern CPUs

Key Ingredients

"Super-Scalar RAM-CPU Cache Compression"
Zukowski, Heman, Nes, Boncz, ICDE'06

- Compress relations on a per-column basis
    - Columns compress well

- Decompress small *vectors* of tuples from a column into the CPU cache
   - Minimize main-memory overhead

Vectorized Decompression

X100 query engine

CPU cache

RAM | **ColumnBM (buffer manager)**

(raid) Disk(s)
Idea:

decompress a vector only

compression:
- between **CPU** and RAM
- Instead of **disk** and **RAM** (classic)

vectorwise

"Super-Scalar RAM-CPU Cache Compression"
Zukowski, Heman, Nes, Boncz, ICDE'06

RAM-Cache Decompression

- Decompress vectors on-demand into the cache
- RAM-Cache boundary only crossed once
- **More (compressed) data cached in RAM**
- **Less bandwidth use**

Multi-Core Bandwidth & Compression

Performance Degradation with Concurrent Queries

- Intel® Xeon E5410 (Harpertown) - Q6b Normal

Column-Oriented Database Systems

VLDB
2009
Tutorial

Conclusion

Summary (1/2)

l Columns and Row-Stores: different?

  l No fundamental differences

  l Can current row-stores simulate column-stores now?

    l not efficiently: row-stores need change

  l On disk layout vs execution layout

    l actually independent issues, on-the-fly conversion pays off

    l column favors sequential access, row random

  l Mixed Layout schemes

    l Fractured mirrors

    l PAX, Clotho

    l Data morphing

Summary (2/2)

- Crucial Columnar Techniques

  - Storage

    - Lean headers, sparse indices, fast positional access

  - Compression

    - Operating on compressed data

    - Lightweight, vectorized decompression

  - Late vs Early materialization

    - Non-join: LM always wins

    - Naïve/Invisible/Jive/Flash/Radix Join (LM often wins)

  - Execution

    - Vectorized in-cache execution

    - Exploiting SIMD

Future Work

l looking at write/load tradeoffs in column-stores

    l read-only vs batch loads vs trickle updates vs OLTP

Updates (1/3)

- Column-stores are update-in-place averse
  - In-place: I/O for each column
  - + re-compression
  - + multiple sorted replicas
  - + sparse tree indices

Update-in-place is infeasible!

Updates (2/3)

- Column-stores use differential mechanisms instead

  - Differential lists/files or more advanced (e.g. PDTs)

  - Updates buffered in RAM, merged on each query

  - Checkpointing merges differences in bulk sequentially

    - I/O trends favor this anyway

      § trade RAM for converting random into sequential I/O

      § this trade is also needed in Flash (do not write randomly!)

    - How high loads can it sustain?

      § Depends on available RAM for buffering (how long until full)

        § Checkpoint must be done within that time

        § The longer it can run, the less it molests queries

      § Using Flash for buffering differences buys a lot of time

        § Hundreds of GBs of differences per server

Updates (3/3)

- Differential transactions favored by hardware trends
- Snapshot semantics accepted by the user community
    - can always convert to serialized
      "Serializable Isolation For Snapshot Databases" Alomari, Cahill, Fekete, Roehm, SIGMOD'08

- Row stores could also use differential transactions and be efficient!
    - Implies a departure from ARIES
    - Implies a full rewrite

My conclusion:

a system that combines row- and columns needs differentially implemented transactions.

Starting from a pure column-store, this is a limited add-on.

Starting from a pure row-store, this implies a full rewrite.

Future Work

- looking at write/load tradeoffs in column-stores

  - read-only vs batch loads vs trickle updates vs OLTP

- database design for column-stores

- column-store specific optimizers

  - compression/materialization/join tricks ⅃ cost models?

- hybrid column-row systems

  - can row-stores learn new column tricks?

    - Study of the minimal number changes one needs to make to a row store to get the majority of the benefits of a column-store

    - Alternative: add features to column-stores that make them more like row stores

Conclusion

- Columnar techniques provide clear benefits for:

    - Data warehousing, BI

    - Information retrieval, graphs, e-science

- A number of crucial techniques make them effective

    - Without these, existing row systems do not benefit

- Row-Stores and column-stores could be combined

    - Row-stores may adopt some column-store techniques

    - Column-stores add row-store (or PAX) functionality

- Many open issues to do research on!
